# Spectral Clustering

Part 3: The Normalized Laplacian

Ng Yen Kaow

#### More constraint for balance

- Further constraints can be added to the eigenvalue system
  - The next problem, Graph Partitioning, will use this strategy
  - However, the resultant eigenvalue system will no longer be standard

# Graph Partitioning Problem

- $\square$  Given edge weight matrix  $W = (w_{ij})$  and vertex mass matrix M with diagonal elements  $(m_i)$ , a 2-partitioning of an undirected graph G = (V, E) is a partition of V into two groups S and  $\overline{S}$  such that  $\operatorname{cut}(S, \bar{S}) = \sum_{i \in S, j \in \bar{S}} w_{ij}$  is minimized under the constraint that  $\sum_{i \in S} m_i = \sum_{i \in \bar{S}} m_i$ , or  $1^{T}Mx = 0$ 
  - If let  $m_i = 1$  for all i, then  $\sum_{i \in S} m_i = \sum_{i \in \bar{S}} m_i$  is the same as  $|S| = |\bar{S}|$ , the balance requirement

## Constrained optimization problem

- □ Minimize  $x^T L x$  where L = D' Wsubject to  $x^T M \in \{1, -1\}$  and  $\mathbf{1}^T M x = 0$ 
  - $x_i \in \{1, -1\}$  and  $\mathbf{1}^T M x = 0$  together enforce balance in the solution

- However, problem is NP-hard
  - Recall that even the minimum bisection problem, where all edges and vertices have the same weight, is NP-hard

## Relaxed Rayleigh quotient version

- □ Minimize  $x^T L x$  where L = D' Wsubject to  $x^T M x = \sum_i m_i$  and  $\mathbf{1}^T M x = 0$ 
  - $x_i \in \{1, -1\} \Rightarrow x^T M x = \sum_i m_i$  but not the other way around
  - Balance no longer enforced but that's the least of our worry for now because instead of the standard eigensystem
- Optimization must now be achieved through solving the generalized eigensystem

$$Lx = \lambda Mx$$

## Relaxed Rayleigh quotient version

- □ Minimize  $x^T L x$  where L = D' Wsubject to  $x^T M x = \sum_i m_i$  and  $\mathbf{1}^T M x = 0$
- $\Box$  Optimize through  $Lx = \lambda Mx$
- $\square$  Since  $L\mathbf{1}=0$ ,  $\mu_k=\mathbf{1}$ 
  - However, eigenvectors in the solutions are not orthogonal but rather,
     M-orthogonal (μ<sub>i</sub>Mμ<sub>j</sub> = 0 for i ≠ j)
    - $\square$   $\mathbf{1}^{\mathrm{T}} M \mu_{k-1} = 0$  fulfilled
- □ Convert to a standard eigenvalue system  $M^{-1/2}LM^{-1/2}x = \lambda x$  to compute

## Convert to $M^{-1/2}LM^{-1/2}x = \lambda x$

- □ Minimize  $x^T L x$  where L = D' Wsubject to  $x^T M x = \sum_i m_i$  and  $\mathbf{1}^T M x = 0$
- Let  $y = M^{1/2}x$ , that is,  $x = M^{-1/2}y$   $x^{T}Lx \Rightarrow y^{T}M^{-1/2}LM^{-1/2}y$   $x^{T}Mx = \sum_{i} m_{i} \Rightarrow y^{T}y = \sum_{i} m_{i}$   $\mathbf{1}^{T}Mx = 0 \Rightarrow \mathbf{1}^{T}M^{1/2}y = 0$

Hence equivalently

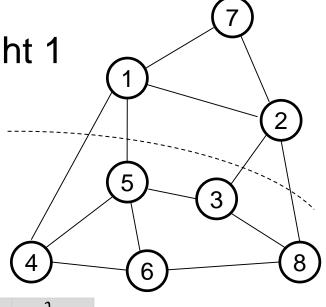

□ Minimize  $yM^{-1/2}LM^{-1/2}y$ subject to  $y^Ty = \sum_i m_i$  and  $\mathbf{1}^TM^{1/2}y = 0$ 

# Convert to $M^{-1/2}LM^{-1/2}x = \lambda x$

- □ Minimize  $yM^{-1/2}LM^{-1/2}y$ subject to  $y^Ty = 1$  and  $\mathbf{1}^TM^{1/2}y = 0$
- □ As 1 is a eigenvector for  $Lx = \lambda Mx$  with eigenvalue 0,  $M^{1/2}$ 1 is a eigenvector for this system with eigenvalue 0 (smallest)
  - Since eigenvectors of this system are orthogonal,  $(M^{1/2}\mathbf{1})\mu_{k-1} = 0$  $\Rightarrow \mathbf{1}^{\mathrm{T}}M^{1/2}y = 0$  fulfilled
  - In fact the eigenvalues for this system are the same as those for  $Lx = \lambda Mx$ , even though the eigenvectors are different (related by  $y = M^{1/2}x$ )

# Generalized eigenvalue system

 First use of generalized eigenvalue system for spectral clustering in

Donath and Homan, "Algorithms for partitioning of graphs and computer logic based on eigenvectors of connection matrices", 1972, IBM Technical Disclosure Bulletin 15(3):938–944

- Also used in Normalized Cut
  - Which is currently almost synonymous with spectral clustering

#### Normalized Cut Problem

Given weight matrix  $W = (w_{ij})$  and weighted degree matrix  $D' = (d_i)$ , the normalized cut of an undirected graph G = (V, E) is a partition of V into two groups S and  $\bar{S}$  such that

$$\operatorname{ncut}(S, \bar{S}) = \operatorname{cut}(S, \bar{S}) \left( \frac{1}{\operatorname{vol}(S)} + \frac{1}{\operatorname{vol}(\bar{S})} \right)$$

is minimized, where  $\operatorname{vol}(S) = \sum_{i \in S} d_i$ , that is, sum of all the weights of the edges adjacent to vertices in S, and  $\operatorname{cut}(S, \bar{S}) = \sum_{i \in S, i \in \bar{S}} w_{ij}$ 

#### **Normalized Cut**

 $\square$  Represent a partition S,  $\overline{S}$  of V with  $x \in \mathbb{R}^n$ , where

$$x_{i} = \begin{cases} \frac{1}{\text{vol}(S)} & \text{if } i \in S \\ -\frac{1}{\text{vol}(\bar{S})} & \text{if } i \in \bar{S} \end{cases}$$

1. 
$$x^{\mathrm{T}}Lx = \sum_{ij} w_{ij} (x_i - x_j)^2 = \left(\frac{1}{\operatorname{vol}(S)} + \frac{1}{\operatorname{vol}(\bar{S})}\right)^2 \sum_{ij} w_{ij}$$
$$= \left(\frac{1}{\operatorname{vol}(S)} + \frac{1}{\operatorname{vol}(\bar{S})}\right)^2 \operatorname{cut}\left(S, \overline{S}\right)$$

2. 
$$x^T D' x = \sum_i d_i(x_i)^2 = \sum_{i \in S} \frac{d_i}{\text{vol}(S)^2} + \sum_{i \in \bar{S}} \frac{d_i}{\text{vol}(\bar{S})^2} = \frac{1}{\text{vol}(S)} + \frac{1}{\text{vol}(\bar{S})}$$

$$1 + 2 \Rightarrow \frac{x^{\mathrm{T}} L x}{x^{\mathrm{T}} D' x} = \mathrm{cut}(S, \bar{S}) \left( \frac{1}{\mathrm{vol}(S)} + \frac{1}{\mathrm{vol}(\bar{S})} \right) = \mathrm{ncut}(S, \bar{S})$$

## Constrained optimization problem

 $\square$  Minimize  $x^{T}Lx$  where L = D' - W

subject to 
$$x_i \in \left\{\frac{1}{\operatorname{vol}(S)}, -\frac{1}{\operatorname{vol}(\bar{S})}\right\}$$
,  $x^T D' x = 1$ , and  $\mathbf{1}^T D' x = 0$ 

- Problem is NP-hard
- Note:

- $\frac{1}{\text{vol}(S)}$ ,  $-\frac{1}{\text{vol}(\bar{S})}$  are not the only possible choices
  - See https://arxiv.org/abs/1311.2492

## Relaxed Rayleigh quotient version

□ Minimize  $x^{T}Lx$ subject to  $x^{T}D'x = 1$  and  $\mathbf{1}^{T}D'x = 0$ 

Through the same reasoning as in graph partitioning problem, equivalently solve

- □ Minimize  $y(D')^{-1/2}L(D')^{-1/2}y$ subject to  $y^Ty = 1$  and  $\mathbf{1}^T(D')^{1/2}y = 0$ where  $y = (D')^{1/2}x$ 
  - $\Box$   $(D')^{-1/2}L(D')^{-1/2}$  is now commonly known as the **normalized Laplacian**

## Shi and Malik (1997, 2000)

- □ Proposed the NP-hard ncut problem
- Found Laplacian for ncut
- Related ncut Laplacian to generalized eigenvalue system, resulting in the now ubiquitous normalized Laplacian
  - However, the first use of the generalized eigenvalue system for spectral clustering was in 1972
- Clustering with multiple eigenvectors (Shi and Malik 2000)

The resultant eigenvectors are less suitable for clustering

have weight 1

© 2021. Ng Yen Kaow

## Theoretical justification

- Why does normalized Laplacian work
  - Probabilistic (random walk) justification by Maila and Shi (2000)
- Why does k-means on multiple eigenvectors work for the normalized Laplacian
  - Ng et al. (2001) show conditions for method to work

## More clustering methods

- Based on the Fiedler vector
  - Sign cut or zero threshold cut
  - Median cut (ensures balance)
  - Sweep/criterion cut
    - Sort vertices by Fiedler vector values and cut at the lowest value of some cost function
  - Jump/gap cut
    - Sort vertices by Fiedler vector values and cut at the point of largest gap
- Based on multiple eigenvectors
  - Simultaneous k-way (Shi and Malik 2000)
  - k-means (Ng et al. 2001)

## **Equivalent Laplacian**

- □ Ng et al. (2001) used  $L' = D'^{-\frac{1}{2}}(W)D'^{-\frac{1}{2}}$  instead of the normalized Laplacian for analysis
  - L' = I L (L = normalized Laplacian)

$$L = D'^{-1/2}(D' - W)D'^{-1/2}$$

$$= D'^{-1/2}(D')D'^{-\frac{1}{2}} - D'^{-\frac{1}{2}}(W)D'^{-\frac{1}{2}}$$

$$= I - D'^{-\frac{1}{2}}(W)D'^{-\frac{1}{2}} = I - L$$

□ Results in the same eigenvectors but eigenvalues become  $1 - \lambda_1, ..., 1 - \lambda_k$
