- Let *U* be a eigenbasis of some Laplacian *L*
- □ Then $U^T x$ is a projection of distribution x on eigenbasis U x and y will be used

where $a_i = \mu_i x$ is the projection onto μ_i

The projected space is $\sum_i a_i \mu_i$

- Let *U* be a eigenbasis of some Laplacian *L*
- □ Then U^Tx is a projection of distribution x on eigenbasis U
- \square An application of U would transform \dot{x} back into x

$$U\dot{x} = \begin{bmatrix} \uparrow & \uparrow & \\ \mu_{1} & \mu_{2} & \dots \end{bmatrix} \begin{bmatrix} a_{1} \\ a_{2} \\ \vdots \end{bmatrix} = \begin{bmatrix} \mu_{11}a_{1} + \mu_{21}a_{2} + \dots \\ \mu_{12}a_{1} + \mu_{22}a_{2} + \dots \\ \vdots \end{bmatrix}$$
$$= \mu_{1}a_{1} + \mu_{2}a_{2} + \dots = \mu_{1}\mu_{1}^{\mathsf{T}}x + \mu_{2}\mu_{2}^{\mathsf{T}}x + \dots$$
$$= (\sum_{i} \mu_{i}\mu_{i}^{\mathsf{T}})x = Ix = x$$

Homework: prove $\sum_{i} \mu_{i} \mu_{i}^{\mathsf{T}} = I$

- \Box Let U be a eigenbasis of some Laplacian L
- □ Then $U^{\top}x$ is a projection of distribution x on eigenbasis U
- An application of U would transform \dot{x} back into x, $U(\dot{x}) = U(U^{T}x) = x$ (obvious since $UU^{T} = I$)
- □ Denote $U^{\mathsf{T}}x$ as F(x) and $U\dot{x}$ as $F^{-1}(\dot{x})$

A convolution of x in the Fourier domain of a graph G is $x * g = F^{-1}(F(x) \odot F(g)) = U(U^T x \odot U^T g)$ where U is the eigenbasis of some Laplacian of G, g is some filter that works on the eigenbasis U, and O is the element-wise (Hadamard) product

□ Suppose
$$\mathbf{U}^{\mathsf{T}}\mathbf{g} = \begin{bmatrix} g_1 \\ g_2 \\ \vdots \end{bmatrix}$$
. Let $g_{\theta} = \operatorname{diag}(\mathbf{U}^{\mathsf{T}}\mathbf{g}) = \begin{bmatrix} g_1 & 0 & 0 \\ 0 & g_2 & 0 \\ 0 & 0 & \ddots \end{bmatrix}$

Then we can write $x * g = U g_{\theta} U^{\mathsf{T}} x$ (shown below)

- Each g_i weights the significance of the eigenvector μ_i
- lacksquare g_{θ} is to be inferred
- This inference task results in the spectral GNNs

$$U^{\top}x \odot U^{\top}g = \begin{bmatrix} a_1 \\ a_2 \\ \vdots \end{bmatrix} \odot \begin{bmatrix} g_1 \\ g_2 \\ \vdots \end{bmatrix} = \begin{bmatrix} a_1g_1 \\ a_2g_2 \\ \vdots \end{bmatrix}$$
$$g_{\theta}U^{\top}x = \begin{bmatrix} g_1 & 0 & 0 \\ 0 & g_2 & 0 \\ 0 & 0 & \ddots \end{bmatrix} \begin{bmatrix} a_1 \\ a_2 \\ \vdots \end{bmatrix} = \begin{bmatrix} a_1g_1 \\ a_2g_2 \\ \vdots \end{bmatrix}$$

Spectral GNN

- The spectral GNN task of learning a function f and filter g for graph G, is to infer f and the coefficients g_1 , g_2 , ..., such that for each x, $f(Ug_\theta U^\top x)$ matches the desired output
 - These GNNs work in the spectral domain as opposed to the spatial domain of the graph
 - lacksquare $g_{ heta}$ is to be independent of the eigenvectors U
 - That is, $g_{\theta}(L) = g_{\theta}(U \Lambda U^{T}) = U g_{\theta}(\Lambda) U^{T} x$ where L is some Laplacian for G
 - $\quad \square \quad$ Of course, $g_{ heta}$ may turn out to be independent of Λ
 - In which case, g_{θ} is inferred solely from the examples
- Hence in spectral GNNs we learn which eigenvectors to use from examples in a supervised learning
 - In spectral clustering we take the eigenvectors of the slowest growth (hence more "global") and perform unsupervised learning with those vectors

- □ However, computing U is $O(N^3)$ and computing U^Tx is $O(N^2)$ ⇒ expensive
- \Box Approximate g_{θ} with Chebyshev polynomials

$$g_{\theta'}(\Lambda) \approx \sum_{i=0}^{K} \theta_i' T_i(\tilde{\Lambda})$$

where

- $\square \tilde{\Lambda} = \frac{2}{\lambda_{\max}} \Lambda I \ (\lambda_{\max} \text{ is the largest eigenvalue})$
- $\Box \theta' \in \mathbb{R}^K$ are Chebyshev coefficients, and
- \Box The polynomials $T_i(x)$ are computed with a recurrence relation
 - $T_0(x) = 1, T_1(x) = x$ (base case)
 - $T_{n+1}(x) = 2xT_n(x) T_{n-1}(x)$

 \Box T_n , the n^{th} order coefficient of the Chebyshev polynomials of the first kind, is $T_n(\cos\theta) = \cos n\theta$

The coefficients can be obtained using the recurrence relation

$$\cos(n+1)\theta + \cos(n-1)\theta = 2\cos\theta\cos n\theta$$
$$\Rightarrow T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x)$$

- □ However, computing U is $O(N^3)$ and computing U^Tx is $O(N^2)$ ⇒ expensive
- \square Approximate g_{θ} with Chebyshev polynomials

$$g_{\theta'}(\Lambda) \approx \sum_{i=0}^{K} \theta_i' T_i(\tilde{\Lambda})$$

where *K* is the number of expansion terms. Then

$$x * g_{\theta'} = Ug_{\theta}U^{\mathsf{T}}x \approx U\left(\sum_{i=0}^{K} \theta_{i}'T_{i}(\tilde{\Lambda})\right)U^{\mathsf{T}}x$$

 \Box Since $T(L) = UT(\Lambda)U^{\top}$

$$x * g_{\theta'} \approx \sum_{i=0}^{K} \theta_i' T_i(\tilde{L}) x$$

- □ Hence we have $x * g_{\theta'} \approx \sum_{i=0}^{K} \theta'_i T_i(\tilde{L}) x$
- □ Furthermore, from the Chebyshev recurrence

$$T_{n+1}(\tilde{L}) = 2\tilde{L}T_n(\tilde{L}) - T_{n-1}(\tilde{L})$$

 \square Denote $\bar{x}_k = T_k(\tilde{L})x$, this becomes

$$\bar{x}_{n+1} = 2\tilde{L}\bar{x}_n - \bar{x}_{n-1} \text{ (or } \bar{x}_n = 2\tilde{L}\bar{x}_{n-1} - \bar{x}_{n-2})$$

- - ...and can be computed in O(K|E|) time from \tilde{L}
- Precompute the K vectors $\bar{x}_0, ..., \bar{x}_K$, with the recurrence relation, and learn the scalars $\theta'_0, ..., \theta'_K$

K = 1 approximations (GCN)

- □ Hence we have $x * g_{\theta'} \approx \sum_{i=0}^{K} \theta'_i T_i(\tilde{L}) x$
- \Box Finally, GCN takes K = 1 to obtain

$$x * g_{\theta'} \approx \theta'_0 x + \theta'_1 \tilde{L} x = \theta'_0 x + \theta'_1 \left(\frac{2}{\lambda_{\text{max}}} L - I_N\right) x$$

- Furthermore let $\lambda_{\text{max}} = 2 \Rightarrow x * g_{\theta'} \approx \theta'_0 x + \theta'_1 (L I_N) x$
- Let θ'_0 and θ'_1 be the parameters to be learned
- Using the unweighted normalized Laplacian, $L = D^{-1/2}(D-A)D^{-1/2} = I D^{-1/2}AD^{-1/2}$, then $x * g_{\theta'} = \theta'_0 x \theta'_1 D^{-1/2}AD^{-1/2} x$
- Further constraint the number of parameters by letting

$$\theta'_0 = -\theta'_1 = \theta$$
, $x * g_{\theta'} = \theta (I + D^{-1/2}AD^{-1/2})x$

K = 1 approximations (GCN)

□ However, since $L = I - D^{-1/2}AD^{-1/2}$

$$\Rightarrow x * g_{\theta'} = \theta (I + D^{-1/2}AD^{-1/2})x = \theta (2I - L)x$$

Then, multiple applications of $\theta(2I - L)$ would result in $\theta^k(2I - L)^k x = \theta^k U(2 - \Lambda)^k U^T x$

where Λ/U are the eigenvalues/eigenvectors for L

(GCN places non-linear functions between layers which we ignore in this derivation)

- L has eigenvalues in $[0, \lambda_{\max}]$ (where $\lambda_{\max} \le 2$ is the largest eigenvalue of L)
 - $\Rightarrow (2 \Lambda)^k$ has range of $[(2 \lambda_{\text{max}})^k, 2^k]$
 - \Rightarrow Exponentially large spectral coefficients at higher k
- □ Solution: Let $\hat{A} = A + I$ and normalize \hat{A} (renormalization)

This gives us $x * g_{\theta'} = \theta \widehat{D}^{-1/2} \widehat{A} \widehat{D}^{-1/2} x$ where $\widehat{D}_{ii} = \sum_i \widehat{A}_{ij}$

How does this affect the spectral coefficients?

K = 1 approximations (GCN)

- □ Compare $\hat{D}^{-1/2}\hat{A}\hat{D}^{-1/2}$ to $D^{-1/2}AD^{-1/2}$ (Ng, Weiss, and Jordan 2001)
 - Eigenvalues of $D^{-1/2}AD^{-1/2}$ range in [-1,1]
 - $\widehat{D}^{-1/2} \widehat{A} \widehat{D}^{-1/2} \text{ differs from } D^{-1/2} A D^{-1/2} \text{ in its self-loops}$ $(\widehat{A} = A + I)$
- A Laplacian with self-loops has a smaller spectrum than one without
 - **Theorem** (Wu *et al.* 2019). Let A (and D) be the adjacency matrix (and degree matrix) of an undirected, weighted, simple connected graph G. Let $\hat{A} = A + \gamma I$, $\gamma > 0$ and let \hat{D} be its degree matrix. Let
 - \square λ_n/λ_1 be the min/max eigenvalues of $D^{-1/2}AD^{-1/2}$
 - $\hat{\lambda}_n/\hat{\lambda}_1$ be the min/max eigenvalues of $\hat{D}^{-1/2}\hat{A}\hat{D}^{-1/2}$ Then $\lambda_n<\hat{\lambda}_1=\lambda_1=1$
 - \Rightarrow Eigenvalues of $\hat{D}^{-1/2}\hat{A}\hat{D}^{-1/2}$ range in $[\lambda,1]$ for some $\lambda > -1 \Rightarrow$ No exponential increase at large k

How legit are GCN approximations

 \square Consider the two approximations of $x * g_{\theta}$ in GCN

1.
$$S_{1\text{-order}} = \theta (I + D^{-1/2}AD^{-1/2})$$
, or

2.
$$\hat{S}_{\text{adj}} = \theta \hat{D}^{-1/2} \hat{A} \hat{D}^{-1/2} \ (\hat{A} = A + I)$$

where θ is a scalar to be learned

Evaluate how well they approximate $x * g_{\theta}$ in the case that $g_{\theta} = \operatorname{diag}(\Lambda)$, that is,

$$x * g_{\theta} = (Ug_{\theta}U^{\mathsf{T}})x = (U\Lambda U^{\mathsf{T}})x = Lx$$

- First, letting $\theta_0' = -\theta_1'$ (case of $S_{1\text{-order}}$) or $\theta_0' = \theta_1'$ would result in $x * g_{\theta'}$ having the same eigenvectors as L, that is,
 - $\theta_0' = -\theta_1' \Rightarrow x * g_{\theta'} = \theta(2I L)x$ \Rightarrow same eigenvectors but eigenvalues become $2 - \lambda$
 - $\theta'_0 = \theta'_1 \Rightarrow x * g_{\theta'} = \theta L x$ \Rightarrow same eigenvalues/ eigenvectors

How legit are GCN approximations

- \Box Use the Karate club graph for L
- Comparison of eigenvectors/ eigenvalues

Filter	Eigenvalues	Eigenvector (corr. to smallest eigenvalue in L)
L	1.71, 1.61, 1.58, 1.57,, .39, .29, .13, 0	32,24,25,2,14,16,16,16,18,11,, 14,14,11,16,14,16,16,2,28,33
$S_{1 ext{-order}}$.32, .24, .25, .2, .14, .16, .16, .16, .18, .11,, .14, .14, .11, .16, .14, .16, .16, .2, .28, .33
$oldsymbol{\hat{\mathcal{S}}}_{ ext{adj}}$	1., .9, .77, .7, .55,,21,22,27, 31,42	.3, .23, .24, .19, .15, .16, .16, .16, .18, .13,, .15, .15, .13, .16, .15, .16, .16, .19, .26, .31

- \blacksquare L and $S_{1-order}$ share the same eigenvectors
- Eigenvectors of \hat{S}_{adj} closely resembles those of L and $S_{1-order}$
- □ Evaluate $MSE(S_{1-order}x, Lx)$ and $MSE(\hat{S}_{adj}x, Lx)$ on randomly generated x
 - \square MSE($S_{1-\text{order}}x$, Lx) = 0.159 (obtained at $\theta \sim 0.1$)
 - $\square \quad \mathsf{MSE}(\hat{S}_{\mathrm{adj}}x, Lx) = 0.166 \text{ (obtained at } \theta \sim 0.07)$
 - \square MSE(random vector, Lx) = 0.413
 - Better than random but lackluster performance due to differences in eigenvalues which were not remedied downstream

GCN properties

- □ GCN as spatial GNN (Gilmer *et al.* 2017)
 - Consider $\hat{S}_{adj} = \theta \hat{D}^{-1/2} \hat{A} \hat{D}^{-1/2}$ $(\hat{A} = A + I)$
 - Rewrite $\theta \hat{D}^{-1/2} \hat{A} \hat{D}^{-1/2} x$ as $\hat{A}HW$ and we arrive at a spatial method
- ☐ GCN as low-pass filter (Wu et al. 2019)
 - As mentioned, $\hat{S}_{adj} = \theta^k U (2 \Lambda)^k U^{\top}$
 - At high k, values of $(2 \Lambda)^k$ for $(2 \Lambda) \ll 1$ diminish
 - □ This often eliminates the negative $(2 \Lambda)^k$ values (for odd k)

Filter	Eigenvalues (using the Karate club graph for L)	
L^6	25.41, 17.54, 15.76, 14.95, 11.26, 9.24, 8.09, 7.31, 6.1, 4.16, 2.43, 1.82, 1, 1, 1, 1, 1, 1, 1, 1, 1, 0.56, 0.42, 0.31, 0.21, 0.16, 0.13, 0.07, 0.05, 0, 0, 0

$\widehat{D} - \widehat{A} = (D + I) - (A + I) = D - A$	(Augmented) Laplacian	[0, 2 max(<i>A</i>)]
$I - \widehat{D}^{-1/2} \widehat{A} \widehat{D}^{-1/2}$	Normalized augmented Laplacian	[0, 2]
$\widehat{D}^{-1/2}\widehat{A}\widehat{D}^{-1/2}$	Normalized augmented adjacency matrix*† (GCN)	[-1, 1]

^{*}Proposed as approximations of the normalized Laplacian (Kipf and Welling. 2016) $_{\odot$ 2022. Ng Yen Kaow [†]Argued to be low-pass filters of the normalized Laplacian (Wu *et al.* 2019 (Fig 2))

More low-pass filters

- □ We have seen that a Laplacian with self-loops has a smaller spectrum than one without (Wu et al. 2019)
- Consider different degrees of self-loops

$$\hat{A}_{\gamma} = A + \gamma I$$

for different values of γ

- The larger γ is, the smaller the spectrum Theorem (Hoang and Maehara, 2019). Let
 - $\hat{A}_{\gamma} = A + \gamma I \text{ for } \gamma > 0$
 - \widehat{D}_{ν} be the degree matrix for \hat{A}_{ν}
 - $\lambda_{\gamma}^{(i)}$ be the i^{th} largest eigenvalue of $\widehat{D}_{\gamma}^{-1/2} \widehat{A}_{\gamma} \widehat{D}_{\gamma}^{-1/2}$

Then for
$$0 \le \gamma' < \gamma$$
, $\lambda_{\gamma'}^{(i)} < \lambda_{\gamma}^{(i)} \le \lambda_{\gamma'}^{(1)} = \lambda_{\gamma}^{(1)} = 1$

Corollary. $\gamma > \gamma' \Rightarrow [\lambda_{\gamma}^{(n)}, \lambda_{\gamma}^{(1)}]$ is smaller than $[\lambda_{\gamma'}^{(n)}, \lambda_{\gamma'}^{(1)}]$

More low-pass filters

- □ Eigenvalues of $\widehat{D}_{\gamma}^{-1/2} \widehat{A}_{\gamma} \widehat{D}_{\gamma}^{-1/2}$ for the Karate club
 - All eigenvalues except
 1 diminishes quickly
 when raised to some
 power
 - Negative eigenvalues will dovetail between negative and positive as the power changes between odd and even numbers
- At some point, the range becomes close to [0, 1]
- \square ...the range continues to shrink as γ increases
